

Battling cancer with fruit concentrate

(Reform 11.03)

Many millions of cells die in our system daily and new ones form as a replacement. Cell division is controlled by a very complex and sensitive “software” with an additional task of repairing early damages on molecular level. However, if the repair-system becomes exhausted it is easy for malignant cells to form. The immune system starts a fight against these now, and tries to eliminate them with all its might, but is not always successful. At this stage the malignant cells are freely circulating in the vascular system, and sooner or later they settle down in one of the organs. There they start an uncontrollable, fast division, which later leads to the development of cancer.

Treating cancer is not an easy task either for the doctor or the patient. Obviously, considerable mental and monetary forces are employed in the world’s research laboratories, for prevention and early diagnosis. Hungarian researchers can also call significant results their own. Professor Janos Mink, for example, developed a method, using which it is possible to diagnose the pathological processes in our system from the chemical compound of our skin and hair with 95 percent accuracy. Meanwhile, Istvan Ember has done animal experiments with a fruit concentrate developed for the purpose of controlling cancer two years ago, to prove the efficiency of the substance. Based on the laboratory reports, there is a good reason to find it probable, that the product prevents cancer development on a genetic level.

The manufacturing company now officially announced: they find it proven by the results of their research, that the prophylactic drink prevents malignant cell growth, and for this they even assume liability.
